# Does intrinsic motivation for work lead to an unbalanced life?

A paper on the effects of intrinsic motivation as passion and a feeling of useful work on work-life balance with the moderating effect of solo self-employment.

## Abstract

Having a good work-life balance is strongly related to life satisfaction across cultures. What leads to a good work-life balance is still being researched. To better understand work-life balance this research will look at the effect of intrinsic motivation. The research question this lead to is: *How does intrinsic motivation affect work-life balance and is this effect moderated by being solo self-employed?* While previous research mostly focused on the effect in limited working sectors, this paper will expand on this by including all working sectors. Two parts of intrinsic motivation will be used in this research. First, intrinsic motivation based on passion for the work. Second, intrinsic motivation based on a feeling of doing useful work. Based on previous research this paper tested for a negative effect of intrinsic motivation on work-life balance. Being solo self-employed is expected to increase the negative effect of intrinsic motivation. This paper uses a binary logistical regression with the data of the European working conditions survey 2021. This survey included 70.000 respondents of which around 24.000 answered all relevant questions for this research. The results found in this paper showed no indication for a negative effect of intrinsic motivation on work-life balance. Contrary, the results showed strong positive effect for passion for work and a feeling of useful work. Demonstrating the similarities between the effect of the two parts of intrinsic motivation for future research. In addition, being solo self-employed did show a decrease on the positive effect of intrinsic motivation on work-life balance. Showing the effect of being solo self-employed to be relevant for future research across working sectors.

## Introduction

'Work and how to balance it with family and social commitments' is an evaluation that everyone has to make in their working life. Work-life balance has been a widely researched topic across disciplines (Casper et al., 2018). Past research has found strong support for good work-life balance being associated with life satisfaction across cultures (Haar et al., 2014). The effect that a bad work-life balance has on productivity on an organizational level has also been thoroughly researched (Sakshi, 2020). The research on 'what causes a bad work-life balance' is primarily focused on organizational policies. In this large collection of research on work-life balance the personal motivation of the worker is rarely considered and especially not with the idea of intrinsic motivation for work having a negative influence.

Having intrinsic motivation for your work can greatly increase the pleasure experienced while working. This will lead people to work extremely hard and work extra-long hours. To get their dream job, people are willing to work these long hours to go the extra mile (Arvidsson et al., 2010). Most people will recognize the experience of losing contact with a friend, as they never seem to have time anymore due to themselves having to commit it all to that new exciting job. The research into this phenomenon of intrinsic motivation is quite limited, except for the study on 'Passionate workers in creative sectors accepting more precarious conditions' which is well documented (Umney & Kretsos, 2015; Arvidsson et al., 2010; Been & Keune 2020). This research shows passionate workers are more likely to accept precarious working conditions. Longer working hours, worse job security and worse pay are worth it to be able to do a job they are passionate about. The connection to work-life balance often fails to be addressed in this research.

In this paper, I will connect the existing research on passion, leading to accepting more precarious working conditions, to the concept of work-life balance and extend the research field by looking at data not limited to a specific working sector. This will add to the existing literature by looking at the effect of passion on work-life balance outside of creative sectors. This paper will look at two parts of intrinsic motivation, the first part being passion found in creative sectors. The second part is about intrinsic motivation based on a feeling of useful work that is found in voluntary workers (Bang & Ross, 2009). These voluntary workers often do not have passion for the job itself but get their intrinsic motivation from, for example, the value it brings to their community.

The idea that precarious working conditions are prevalent with passionate workers in creative sectors is, as mentioned above, well researched. This research wants to add to this existing literature, the idea that this effect will be stronger if someone already has a more precarious working position by being solo self-employed. When solo self-employed the increased amount of flexibility and

autonomy can lead the effect of being “always on” (Hilbrecht & Lero, 2014). This means always having to pick up the phone and often working late to catch up with work. Balanced well this can work positively, when not this increases precarity. When self-employed someone is more enabled to accept extra working hours and work while sick.

In sum, this paper will look at the effect of intrinsic motivation, as passion for work and as having the feeling of doing useful work, on work-life balance moderated by if someone is solo self-employed. This all leads to the research question of this paper:

*Research question: How does intrinsic motivation affect work-life balance and is this effect moderated by being solo self-employed?*

## Theory

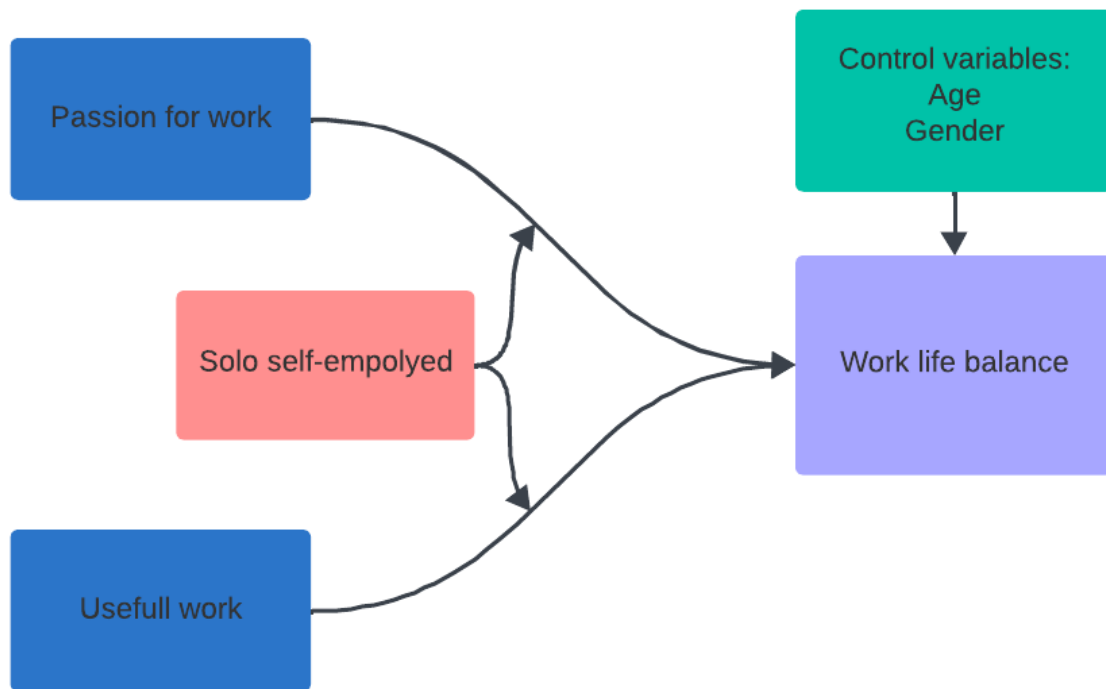

Figure 1: Research model

To answer the research question of this paper the model shown in figure 1 was created. This model shows the main relation of two parts of intrinsic motivation, passion for work and useful work, to work-life balance. It also shows a moderation effect for being solo self-employed. How these variables are expected to relate to work-life balance will be explained in the following paragraphs.

### Work-life balance

Work-life balance has been a widely used term in research for a long time now. Not only is the term very popular in research, it has become a commonly known concept for many. Generally it is agreed upon that work-life balance is a convenient shorthand for what the term commonly refers to: work and the rest of life (Guest, 2002). What kind of balance it refers to has been a lot more ambiguous. Balance has been used in many different ways like representing satisfaction or effectiveness (Casper et al., 2018). Casper et al. (2018) also describes the most common element in all definitions, the workers own evaluation. It is a personal experience off how well their work and non-work activities fit together, combined with the importance that the person places on the different parts of life. In this research I will focus on the experience of how well working hours fit in with the family and social commitments. In conclusion the term work-life balance refers to the experience of a person on how well work and non-work activities fit together in their life.

Having a good work-life balance is dependent on whether you think that you can do your work well and still be able to commit enough to family and social commitments. The factors that are generally associated with having a good work-life balance are the amount of working hours and work stress spilling over in to non-work times (Guest, 2002). Having an unstable work life is heavily related to the concept of precarity. Precarity references to the instability and uncertainty of a workers life (Hewison, 2016). Certainty about working hours is also a big factor in having good work life balance (Umney & Kretsos, 2015). Having precarious working conditions will lead to not being able to build up a consistent commitment to the non-work parts of life.

The question that this creates is: Why would someone take on a job at the expense of their other priorities in life? This question does of course not have a singular answer. There are many different parts of life that influence this choice or maybe it is not even a choice. As shown in the research model the main effect on work-life balance that this paper will look at is intrinsic motivation.

### Intrinsic motivation

Being motivated is to be moved to do something (Ryan & Deci, 2000). Intrinsic motivation and extrinsic motivation are the two commonly known sides of motivation. Extrinsic motivation is related to external factors for example economic benefit or status. Therefore it is always dependent on an evaluation if it is worth doing something based on the reward. Intrinsic motivation is the opposite to this and relates to activities where the goal is the activity itself (Fishbach & Woolley, 2022). This same distinction can be made for motivation for work. If someone is only extrinsically motivated to do a job the reward has to be equal or larger than the effort put in to the work. When the work is inherently satisfying, the reward for the work done does not have to be equal to the sacrifice necessary to do the work. This can lead to precarity and long working hours as people, who are inherently motivated for work, can legitimize through this motivation the neglect of their work life balance (Umney & Kretsos, 2015).

For the purposes of this paper I will look at two different parts of intrinsic motivation. First I will look at the literature of passion on work-life balance through precarity as the first part of intrinsic motivation. After looking at the effects of passion on work-life balance I will look at a second part of intrinsic motivation, which is Intrinsic motivation based on the feeling of doing useful work.

### Passion

The first part of intrinsic motivation I want to discuss is the concept of passion. Having passion for work is commonly found in creative sectors where people often describe their job as being their hobby too (Been & Keune, 2019). This results in the effect that the worker gets more value out of the

work than they are being paid. This creates the effect that these workers will accept lower pay and more precarious working conditions to stay in the market and continue doing their jobs (Umney & Kretsos, 2015; Been & Keune, 2022). Even though these workers are underpaid and overworked, they often report a high level of satisfaction as shown by a study of the Milan fashion industry by Arvidsson et al. (2010). In this previously mentioned research into passionate workers it has been found that sometimes the precarious working conditions are exactly what the workers want as it comes with flexibility and freedom. Even though these workers may prefer these more precarious working conditions it still leads to working longer hours under more stress. To uphold their standard of living is very hard, due to the long workdays and lower pay. Despite that passionate workers are willing to accept the precarious working conditions and long hours, which leads to having less time for non-work activities. This means that in these creative sectors the passion of workers leads to a negative effect on their work-life balance. Passion is mainly researched in creative sectors but the effect of increasing work precariousness should be present in all sectors. (Umney & Kretsos, 2015). It is argued by other authors that the effect of passion is because of specific market characteristics (Been & Keune, 2019). The project based structure of the market and the importance of increasing a portfolio would lead people to take on low paying jobs. While these specific market conditions do increase the negative effect of passion. The market conditions do not cause but increase the effect. This effect will be mentioned later on in the form of solo self-employment. Other research shows us that the creative sectors are not the only place where people find the negative effect of passion for the job. Though the creative sector is where being passionate about work is the most present, the same effect of passion for work can be found in other sectors for example with people working to conserve nature (Sandiford & Green, 2020). To test if the negative effect of passion on work-life balance can be found across the labor market the first hypothesis of this paper is:

*Hypothesis 1: Passion for work has a negative effect on work-life balance.*

### **Useful work**

Passion is not the only part of intrinsic motivation. A second part of intrinsic motivation that this paper looks at is based on a feeling of doing useful work. Passion in research as described in the previous paragraph only covered creative sectors where the work is an extension of the workers own interests. In these studies the creative sectors that were researched were game design, music and fashion. In this second part I want to include a different part on intrinsic motivation to the study that can be found in volunteer work. Volunteers are almost always intrinsically motivated to do the job but not due to a pure passion for the job they are doing (Bang & Ross, 2009). Different motivations are described by Bang and Ross (2009) and a common theme seems to be that these volunteers want

to be part of a community or improve a community or activity that they already like. Similar to this Bidee et al. (2017) finds that volunteers in healthcare organizations also derive intrinsic motivation from a feeling of competence and inclusion in the effectiveness of the team. In these cases the motivation is not the enjoyment of the work but it is the feeling of usefulness of the work. Fishbach and Woolley (2022) describes a form of intrinsic motivation where the goal is so inherently related to the job that the person becomes intrinsically motivated to do the job. This kind on intrinsic motivation describes how the goal motivates the work, for example a football coach will be motivated to keep teaching and organizing for the club while getting barely any compensation for the work. This is different from external motivation as it is not about the personal benefit to the person but only the personal enjoyment of the work done well for the people or community that they value. This perspective is a large part of the intrinsic motivation for volunteer workers (Bang & Ross, 2009). It is this kind of intrinsic motivation that I want to include in the study, to see if the negative effect from intrinsic motivation based on passion also extends to a different part of intrinsic motivation based on the feeling of doing useful work. This leads to the second hypothesis of this paper:

*Hypothesis 2: Having a feeling of doing useful work has a negative effect on work-life balance.*

### Moderation effect of solo self-employed

People who are solo self-employed choose a job with more flexibility. When self-employed, an individual has more agency over working hours and their income. As Annink and Dulk (2012) showed in a study about self-employed women in the Netherlands this can, when well-managed, lead to a better balance between work and personal life. When setting the right goals, women in the study were found to be better able to fulfill their personal wishes and aims for their personal and working life. Hilbrecht and Lero (2014) also find that the autonomy of being self-employed, when coordinated as a couple, can bring more possibility to attend family leisure time activity and include children in their life. This literature does attach an asterisk to this positive effect of self-employment. The increased autonomy can in other cases also show its negative side. One of the downsides mentioned by Hilbrecht and Lero (2014) is the effect of being “always on”. There are no strict working hours and tasks that need to be done as soon as possible. So when solo self-employed the job can interfere through calls outside off planned working times, late hours and having to work while sick. When solo self-employed, the increased amount of flexibility goes hand in hand with precarity (Khan & MacEachen, 2024). This results in someone who is solo self-employed being more susceptible to the effect of neglecting other parts of life. With the increased amount of autonomy comes precarity. The negative effect of intrinsic motivation on work-life balance is as described above, due to someone who is more intrinsically motivated accepting lower pay and worse working hours to get or keep their

preferred job. The increased precarity of solo self-employment creates the possibility for someone to more easily accept the worse pay and working hours. This effect of the autonomy of solo self-employment increasing the negative effect of intrinsic motivation leads to the final hypothesis.

*Hypothesis 3:* Intrinsic motivation has a stronger negative effect on work-life balance when someone is solo self-employed.

### Control variables: Age and Gender

This paper will include the two control variables of age and gender. These control variables have been included as they have strong correlations with intrinsic motivation, work-life balance and household income.

First, age has a strong effect on work-life balance. The work-life balance of a young worker looks significantly different from the work-life balance of a person about to retire. For example, an older worker might have plenty of time to work long hours as the children are already out of the house while a younger worker who might have just started their job, is trying to start a family also and still want regular contacts with study friends. Older workers also had more time to establish a solid network while younger workers still need time to establish themselves within a network.

Second, gender has a big effect on work-life balance due to societal expectations. As shown by Emslie and Hunt (2008) that the effect of children significantly impacts the lives of both man and women. The difficulties of sustaining their work life balance lasted far longer and was more complicated for women. While still needing more research it has already been shown that gender can have a big impact in sectors with high amounts of passion (Michie & Nelson, 2006).

## Methodology

### Data and procedure

The dataset used in this research is the data from the European Working Conditions Survey 2021 (EWCS). The data is collected for Eurofound, which is the European foundation for the improvement of living and working conditions. The background to this survey starts in 2020 the scheduled survey done with face-to-face interviews had to be canceled due to the COVID-19 pandemic. In 2021 Eurofound tested a methodological experiment by contacting some of the respondents over the phone and taking the survey. Based on this experiment Eurofound could plan the extraordinary 2021 survey that was held by using a telephone survey. The population of the survey was expanded to 70.000 workers across 36 European countries. This includes the EU member states, the United Kingdom, Norway, Switzerland, Albania, Bosnia and Herzegovina, Kosovo, Montenegro, North Macedonia and Serbia. Per country between 1.000 and 4.200 were interviewed. The survey covered 54 languages including national language variations. The sample is representative of everyone aged 16 or older. The respondents were selected by random phone number generation to get a random sample from the population. The goal of the survey was to create a representative survey to create a comparable and representative dataset on job quality at the time. To create a complete and representative survey Eurofound accounted for non-response by giving a larger weight to underrepresented groups and smaller to overrepresented groups.

The procedure of the interview went according to a pre-planned questionnaire that followed one of six paths. The interview started with a general explanation of the goal and procedure of the interview. The interview would last a maximum of twenty minutes. Of these twenty minutes the first twelve were used to answer the core questions of the interview that all participants were asked. After these questions, the second part of the interview which lasted for about four minutes would cover two out of the three possible modules. The final part of the interview also lasted for about four minutes. One out of two modules would be asked of the respondent. This would mean that the modules in the second part of the interview were asked to around sixty-seven percent of respondents and the modules in the final part to half of respondents. Due to the different modules not all respondents can be included in this research. Of the more than 70.000 respondents around 23.000 could be used in the regression analysis for this paper.

## Operationalisation

In this paragraph, I will talk about all the variables that are used in the research for this paper.

### **Work life balance**

The variable work-life balance was measured by one question called: Q44 *Work\_life\_balance*. The question that was asked was: In general, how well do your working hours align with your family or social commitments outside of work? The different response options were: from 1 to 4. 1 is Very well, 2 is Well, 3 is Not very well, 4 is Not at all well. A change made to *Work\_life\_balance* was to mirror the answer possibilities so that a low answer means not being able to align work with family and social commitments and four means being very well able to do so. The recoded variable is called *Work\_life\_balance\_SM\_mirror*. The answer possibilities are so coded that 1 means not at all well, 2 not very well, 3 well, and 4 very well. This recoded variable is then recoded again into a dummy variable to be able to do the binary logistical regression. *Dummy\_WLB\_SM\_mirror* coded so that 1 and 2 are recoded to 0 and 3 and 4 recoded to 1. This creates the dummy where 0=bad work-life balance and 1=good work-life balance

### **Useful work and passion for work**

For the two parts of intrinsic motivation the variable *useful work* and *ethusiastic about work* are used. First, the variables before they were combined were Q61J [*useful\_work*] and Q90B [*eng\_enthusiastic*]. The question asked for useful work was: You have the feeling of doing useful work. With the response options: Scale from 1 to 5, 1 is never, 2 is rarely, 3 is sometimes, 4 is often, 5 is always. Enthusiastic about work, the variables that represent passion was asked with the questions: I am enthusiastic about my job. With the response options: Scale from 1 to 5, 1 is never, 2 is rarely, 3 is sometimes, 4 is often, 5 is always. Both variables have been centered for the regression. This was done to decrease multicollinearity and enable interpretation of the interaction effect of the moderating variable.

### **Solo self-employed**

The variable *solo self-employed* was created based on the recoded variable *emp\_stat\_lt*. For this variable the answers to multiple question were recoded so that there are 3 answer options: 1= self-employed with employees 2=self-employed without employees and 3=employee. This variable was for the purposes of this paper recoded again where answer option 1 and 3 were combined. This paper focusses specifically on solo self-employed workers because category 1 included a wide range of situations that did not reflect the precarious position of someone who is solo self-employed. After the recoding the two categories remaining were: 0=not solo self-employed 1=solo self-employed.

## Age

The only change to the variable age was that it had to be centered for the regression, all ages were included in the population of the research. The name of the variable was SCR\_Age [age]. The question asked to the respondents was: Starting with yourself, how old are you?

## Gender

The name of the variable gender was: Q2new [sex]. The question asked was: Would you describe yourself as 1: Male 2: Female 3: Or would you describe yourself in another way? For the regression a recoded version of this variable was used where the third category was equally distributed among the two categories of male and female.

## Research-structure

The research-structure of this paper to answer the hypothesis presented in theory section of the paper will be discussed in the following section. As described earlier the dataset that was used for this research was the European Working Condition Survey 2021. This dataset was imported in to Spss to do a regression analysis. A multiple logistical regression analysis was chosen to answer the following hypothesis because the assumptions of linear regression could not be met.

*Hypothesis 1: Passion for work has a negative effect on work-life balance.*

*Hypothesis 2: a feeling of doing useful work has a negative effect on work-life balance*

*Hypothesis 3: Intrinsic motivation has a stronger negative effect on work-life balance when someone is solo self-employed.*

These hypothesis were tested with a multiple logistical regression analysis that was divided into five blocks. The dependent variable of all blocks is the variable work\_life\_balance. In the first block only the control variables age and gender are added. In the second block the variable passion\_for\_work\_centerd was added to test for the first hypothesis. In the third block the variable passion\_for\_work is added again and the variable usefull\_work\_centerd was added as the second hypothesis takes into account both sides of intrinsic motivation. To answer the final hypothesis block four and five are used. In block four has all variables included that are in block three and added to this moderating variable of solo self-employed. In block five the interaction variables of useful work and passion for work are added. So in sum five blocks of multiple regression analyses have been done. The first block is to add the control variables. The second block to answer the first hypothesis, the third block to answer the second hypothesis and the fourth and fived block to answer the third hypothesis.

## Results

### Descriptive statistics

In this section, I will present the results of this paper. In the following chapter, I will first present a summary of the important values in table 1. In the succeeding section, I will describe what regression model has been used and when different variables were added to the model. Then the model fit of the regression model will be discussed. Finally, in the hypothesis testing I will talk about the results and if these match the expectations formulated in the hypothesis.

*Table 1: Descriptive statistics of variables in analysis. Mean (Standard deviation), minimum, maximum and total responses.*

Variable	Mean (Standard deviation)	Minimum	Maximum	N totaal
Age	0,991(12,281)	-25	43	35709
Gender (1=Male 2=Female)	52,5% Male 47,5% Female	1	2	35709
Work Life- balance (0=bad WLB 1=good WLB)	18.1% Bad WLB 81.6% Good WLB	0	1	35778
Passion for work	,000(,981)	-2,98	1,02	35778
Useful work	,000(,817)	-3,43	,57	23937
Solo selfemployed (0=no 1=yes)	91,9% No 8,1% yes	0	1	35778

Table 1: Univariate statistics. The variable passion for work, useful work and age have been centered.

#### The relevant statistic in table 1.

Table 1 shows the descriptive statistics for all included variables in the regression model. The dependent variable work-life balance is very unevenly distributed. To get a better interpretation I have changed the cut-off value for the classification table to match the very skewed dependent variable. This more clearly shows the changes for every block of the regression. The second thing that is notable in table 1 is that the variables age, passion and intrinsic motivation have been centered. This is to be able to test the moderation effect. This change to the variables also leads to less concern about multicollinearity. Also shown in table 1 is the very skewed variable of solo self-employed. Solo self-employed is the most one-sided variable in this regression but passion for work and useful work are also unevenly distributed. This leads to the final notable observation shown in table 1, which is the very high sample test size for the regression. This very high sample test size means that even relatively tiny groups still include a reasonable amount of respondents. The lowest number of respondents for a variable is 23937. This is the population the regression will use.

## Research model

For the regression a logistic regression with 5 different blocks was created. This is to add in every block only 1 new effect to the model. Model 1 only the dependent variable work-life balance and the control variables age and gender are added. In model 2 passion for work is added to this model. In model 3 the variable useful work is added. In model 4 the variable solo self-employed is added. In the last block, model 4, the interaction variables are added.

Table 2: Results of binary logistical regression with work-life balance as dependent variable.

Variable	Model 1		Model 2		Model 3		Model 4		Model 5	
	B (Se)	Odds-ratio	B(Se)	Odds-ratio	B(Se)	Odds-ratio	B(Se)	Odds-ratio	B(Se)	Odds-ratio

Table 2: \*significant at p<0,05 \*\*significant at p<0,01.

## Model fit

First of all no outliers have been removed for the regression results shown in table 2. I have decided to not remove any outliers because when calculating the leverage values it gave particularly high scores to respondents that were solo self-employed and scored very low on passion and useful work. As mentioned above these variables are all very skewed to one side. Respondents that belong to the smaller groups within these variables are shown as outliers. I do not think that this is the case as the variables used in this paper are not continuous variables with a possibility of unrealistically high scores but scales of 1 to 5 and in the case of solo self-employed a dummy. This shows that a solo self-employed person who is not passionate or feels like he is doing useful work is very rare. It should not be taken out of the dataset as it is not an unrealistic result. How the results would have changed with outliers taken out will be shown in appendix 3.

The Hosmer & Lemeshow test is most of the time a good way to test the validity in a logistic regression. The test is significant for every block of the model but this does not show that the model has a bad fit as in this case the very high N leads to a significant Hosmer & Lemeshow test. To see what the Hosmer & Lemeshow indicates, I looked at the contingency table also added in appendix 2. This table indicated that the difference between the expected and observed results were not very big. So to get a good idea of the model fit the Hosmer & Lemeshow is not reliable in this case. For the model fit the classification table cut off has been changed to give a better perspective of the effect of the different models. The classification table now shows the changes in the predictions of the total predicted correctly with the cutoff on 0.8. The model does not improve a single time according to the classification table. Based on the  $-2\log$  likelihood (indicated as  $-test$ ) values model 1, 2 and 3 have very significant improvements over the previous model. While the additions in model 4 and 5 were only smaller improvements but still show to be significant.

## The hypothesis testing

*Hypothesis 1: Passion for work has a negative effect on work-life balance.*

The first hypothesis predicts that someone who is more passionate about their job will have a worse work-life balance. This relationship is tested in model 2 where the effect of passion for work is controlled for age and gender. As shown in table 2 the addition of passion shows significant improvement in the model. Also indicated in table 2, the given slope for passion for work: ( $b=0,333$ ,  $p<0,01$ ). This result indicates a positive direction, which means that more passion for the job relates to a good work-life balance. According to this result, a person with passion for their job has a better work-life balance than if he did not have passion for his job. Table 2 shows that this is a significant positive effect. This positive effect is the opposite of what the hypothesis predicted. Hypothesis 1 has to be rejected based on this result. The rejecting of the hypothesis means that there is evidence

found to support the idea that being passionate about work means you have a worse work life balance.

*Hypothesis 2: A feeling of useful work has a negative effect on work-life balance.*

The second hypothesis predicts that a person with a bigger feeling of doing useful work will have a worse work-life balance. This is tested in model 3 where useful work is added to the variables of model 2. Table 2 shows that the variable useful work ( $b=0,114$ ,  $p<0,01$ ) has a significant effect and that model 3 is a significant addition to model 2. The effect of useful work shown in table 2 has the same positive effect as passion for work. This means that a person with a large feeling of doing useful work would likely have a better work-life balance than if he did not. Hypothesis 2 is not supported as the results found do not correspond with the predicted negative effect. Passion for work and the additional useful work both have a significant positive effect in model 3. While the effects do not show the expectation of the hypothesis the similarity do align with the theory of both being a part of intrinsic motivation.

*Hypothesis 3: Intrinsic motivation has a stronger negative effect on work-life balance when someone is solo self-employed*

Solo self-employed is the moderating variable in the regression analysis. The hypothesis therefore says just like hypothesis 2 that the two parts of intrinsic motivation will have a negative effect on work-life balance. The effect added in hypothesis 3 is that for people who are solo self-employed, this effect will be stronger. We do not find the negative effect of intrinsic motivation predicted in this research and therefore hypothesis 3 cannot be supported. The added variable of solo self-employed still shows an added effect. The effect found by the interaction variable shown in model 5 in table 2 is negative. This means that the positive effect of the two parts of intrinsic motivation is smaller for someone who is solo self-employed. This does match with the prediction in the hypothesis that the solo self-employed have a worse score on work-life balance. This effect of the interaction variable of useful work is significant while the interaction variable of passion for work is not. This shows that the positive effect of intrinsic motivation found in the results is significantly less for someone who is solo self-employed.

## Conclusion and Discussion

The purpose of this paper was to answer how intrinsic motivation for work influences someone's work-life balance. To answer this question three hypotheses were created. First, this research tested for a negative effect of passion for work on work-life balance that was found in literature. The theory for this negative effect was that the time a person balances between their personal and working life would fall out of balance because passionate working will take on overtime or accept lesser payment for their work. This was tested across all work sectors while previously only tested in different creative sectors. The hypothesis was that passion for work had a negative effect on work-life balance. Second, to answer the research question and include a wider part of intrinsic motivation I included a part of intrinsic motivation based on a feeling of work well-done. This leads to the second hypothesis that a feeling of work well done also has a negative effect on work-life balance. Finally I hypothesized that the negative effect of the two parts of intrinsic motivation would be stronger for someone who is solo self-employed. The results showed that no hypothesis could be supported. The effect found by the analysis showed the opposite effect of what was predicted. This means that the argument based on sacrificing time and financial stability does not hold up. The effect the results indicate is the higher someone scored on the two parts of intrinsic motivation the better their work-life balance seems to get. For the solo self-employed worker the positive effect of intrinsic motivation did seem to be smaller but not to a significant degree. To sum up, this paper could find no support for the theory that more intrinsic motivation for a job will lead to a worse work-life balance. Why the theory did not match with the result will be discussed in the following paragraph.

There are two possibilities to review why the theory did not align with the results. First, the results found are correct but the expectations were not accurate. In the theory section of this paper about intrinsic motivation, I mentioned that previous research on the effect of passion on work-life balance predominantly looked at different creative sectors. I expected the effect to translate to all sectors but this was not found in the results. Looking at all sectors combined the results of this paper found the opposite effect. The more intrinsically motivated a person was the better their work-life balance. As presented in the theory section of passion for work, Been and Keune (2019) also argue that the nature of creative sectors being very project-driven with low job security increases precarity. I argue that this increases the negative effect of passion for work, not a cause it and go on to show the negative effect of intrinsic motivation being found outside of the creative sector. The increasing of the negative effect of intrinsic motivation might be so strong that outside of the creative sectors the negative effect of passion for work is too small to find. Although this would explain why the results did not find the expected negative effect, it does not explain the significant positive effect. Furthermore,

the effect of intrinsic motivation on work-life balance I found was positive for solo self-employed respondents who also have very precarious working conditions. How intrinsic motivation has a positive effect on work-life balance and why this effect is not found in creative sectors is an interesting point for future research.

The second reason that the theory and results of this paper do not align could also be that the methodology of the paper is not good enough that even if the expectations were correct the results would not show it. The research model includes variables for a feeling of useful work and passion for work to represent two parts of intrinsic motivation. Having included part of intrinsic motivation this research limits the conclusion that can be drawn from the results. For future research expanding on this to include a combined extensive latent variable for intrinsic motivation would improve on this. This was not done in this research as only two parts of intrinsic motivation were included to see if the effect of a feeling of useful work to inspire intrinsic motivation was the same as the effect of passion for work. Including intrinsic value as a combined variable would also not have been wise to do for this paper as the variables work well done and passion for work did not score high enough on Cronbach's alpha ( $N = 3$ ;  $\alpha = .542$ ) as they did not include enough information to represent the full extent of intrinsic motivation.

While this research left room for improvement for future research, as described there were also findings that might be interesting to include in future research. While the hypothesis of the moderation effect of solo self-employment could not be accepted due to the main effect of intrinsic motivation not going according to expectation. The results showed the effect of solo self-employment to align with the expectation based on the arguments presented. As the results showed someone being solo self-employed to have a smaller positive effect on work-life balance. For future research into the effect of intrinsic motivation on work-life balance including the effect of solo self-employment is important. The effect has extensively been shown within creative sectors where flexibilization and solo self-employment is especially prevalent (Been & Keune, 2022). Now it has also shown to be relevant when looking at all working sectors combined. Finally while this research could not combine the two parts of intrinsic motivation this paper has done a step towards the combination of research of different parts of intrinsic motivation. Although this paper could not show the expected effect across sectors, it did find the same effect in both parts of intrinsic motivation. These similarities of the effect on work-life balance between intrinsically motivated workers based on passion for the work and a feeling of useful work can be a building block in wider research on the effect of intrinsic motivation across different parts of the labor market.

## Recoding of the variables to exclude non answers.

As most clearly shown in the histogram of the variable age. The variables still have the system missing respondents included. The change made to all variables was to recode the answer options - 777 (Not applicable) -888 (Does not know an answer) and -999 (Refusal to answer) as system missing to not get weird outliers and skewed results. This change was made to all variables and will not be individually mentioned again. After the recoding the letter SM were added to the changed name of some of the variables to indicate new cases labelled as system missing. The variable work-life balance is shown first and has also been recoded to be mirrored. This was done so that the answer options were ordered by increasing value to improve readability of the results. After the recoding the value 1 means a bad work-life balance and 4 means a high work-life balance. The variable solo self-employed is shown separately later in this appendix.

## The variable solo self employed

The variable solo self-employed was created for the original variable emp\_stat\_it. This is already a combination variable included in the dataset. This variable was originally created for two separate questions where first the question was asked, if you were self-employed. When the answer was yes, a second question was asked, if you have employees working for you. These two question were combined in the variable to create three groups. 1: self-employed with employees 2: Solo self-employed 3: Employee. The descriptive and frequencies statistics are shown in the following tables.

```

## Recoding to create the variable solo self-employed

As mentioned above the variable emp\_stat\_lt was already a recoded variable included in the database. This recoding included showing non-answers as system missing. For the purpose of this paper the variable does have to be recoded to a dummy where 0: Not solo self-employed and 1: Solo self-employed. This recoding also mirrors the original variable to improve the readability of the results for the interpretation. The frequency and descriptive statistics of the variable after recoding are shown following tables and figure.

```
*Recode selfemp in to solo self emp.
RECODE emp_stat_lt (3=0) (2=1) (1=0) (ELSE=Copy) INTO Solo_selfemp.
VARIABLE LABELS Solo_selfemp 'Solo_selfemp'.
EXECUTE.
*Statistics solo self emp.
FREQUENCIES VARIABLES=Solo_selfemp
  /STATISTICS=MEAN
  /BARCHART FREQ
  /ORDER=ANALYSIS.
```

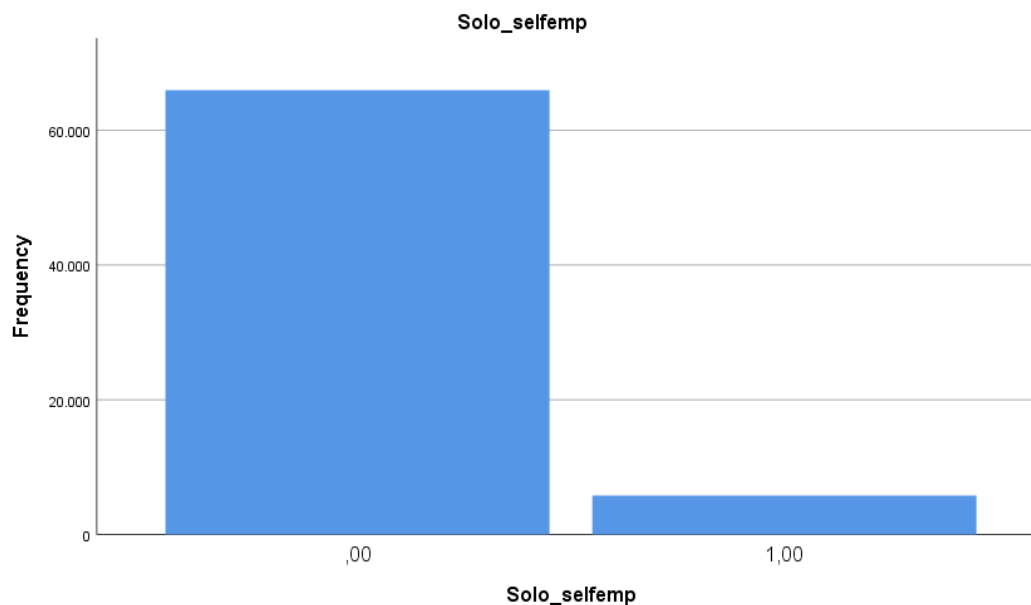

### Statistics

Total		71758	100,0		

## Creating the dummy for work-life balance

It was concluded that the variable work life balance needed to be recoded as only a binary logistic regression could be done due to the very skewed nature of the variable. This was done with the following recoding in to different variable where the value 1 and 2 are recoded to 0 and 3 and 4 to the value of 1. This results in 0 representing bad work-life balance and 1 good work-life balance. The variable remain very skewed as most people report a good work-life balance.

```
*Making dummy work life balance because no ordinal regression.
RECODE Work_life_balance_SM_mirror (1=0) (2=0) (3=1) (4=1) INTO
Dummy_WLB_SM_mirror.
VARIABLE LABELS Dummy_WLB_SM_mirror 'Dummy_WLB_SM_mirror'.
EXECUTE.
*Statistics WLB dummy.

## Recoding continuous variables to be centred.

To make sure a problems with multicollinearity stayed to a minimum and a moderation could be done in the regression analysis the continuous variables age, passion for work and useful work are centred.

```
*Centreren age.
DATASET ACTIVATE DataSet1.
COMPUTE Age_centerd_SM=Age_SM - 41.
VARIABLE LABELS Age_centerd_SM 'Age_centerd_SM'.
EXECUTE.
*Centreren passion for work.

### Coding the interaction variables.

In the regression analysis the moderating effect of solo self-employment is included. To create the interaction variables of passion for work and useful work with solo self-employed the following coding was done.

\*Interactievariabele maken.

```
COMPUTE Passion_for_work_x_SSEMP=Passion_for_work_centerd * Solo_selfemp.
EXECUTE.
```

```
COMPUTE Usefull_work_x_SSEMP=Usefull_work_centerd * Solo_selfemp.
EXECUTE.
```

## Appendix 2

### The logistical regression coding

A binary logistical regression that contains 5 different blocks was done. In the first block only the control variables and the depended variable are added. In block 2 the variable passion for work is added to answer hypothesis 1. In block 3 the variable useful work is added to answer hypothesis 2. In block 4 solo self-employed is added and in block 5 the two interaction variables of useful work and passion for work are added to answer hypothesis 3. The N is 23811 because those are all the participants that have answered the questions necessary for every variable.

For the model fit the classification table, the Hosmer and Lemeshow test and other tests are added to test for the improvement and reliability of the model. For the classification table the cut off value was changed to 0.8 to reflect the skewed dependent variable. For the Hosmer and Lemeshow the contingency table has been added to the appendix to give context to the high significant values of the test.

## Cronbach's alpha and correlation

To discuss the potential of a combined variable for intrinsic motivation out of useful work and passion for work the correlations and Cronbach's alpha were calculated. These results show that the two variables do correlate to each other they are not enough to create a relevant combined variable to represent intrinsic motivation.

- a. Not assuming the null hypothesis.
- b. Using the asymptotic standard error assuming the null hypothesis.
- c. Based on normal approximation.

### Appendix 3

For the logistic regression there is no way to test the assumption with a statistical test.

The following part of the appendix regards outliers, why they were not excluded and what would have changed if they were.

The calculated leverage score for  $\frac{3p}{N} = 0.001007937$ . Following this guideline would have meant excluding thousands of cases where way more than half was solo self-employed, while only 8% is solo self-employed in the wider dataset. After seeing this similarity I looked at specific cases and why they were shown as outliers. The conclusion of this was that the respondents who were seen as outliers were not any ridiculous case but were part of the smaller groups in the very skewed proportions of the variables solo self-employed, passion and useful work. The continuous variables used in this paper only have scales of 1 to 5. This makes it so that there are not real outliers that need to be excluded as every answer option and combination is a realistic scenario. It is still interesting to see what the excluding of some of the more extreme outliers changes. Because of this I looked at the difference between cases and their leverage values and concluded that around 67 the last sudden bigger decline in leverage value takes place. While excluding the 66 cases with the biggest leverage value several things changed. Most notably the previously barely significant interaction effect of useful work disappeared. The effect of the variable useful work and passion for work got smaller. As shown in the final table of block 5 of the logistic regression in appendix 2 the value before excluding outliers of the interaction variable of useful work was  $-196$ . This decreases to  $-91$  when excluding the outliers. The effect was seen as significant before the exclusion of the outliers and not after.

For the appendix of the logistical regression without the outliers the contingency table for the Hosmer & Lemeshow test was not included as it did not add to the relevant information of the appendix. Also some minor changes were made to exclude irrelevant information for the variable names to create more visual clarity.
